

Mobile Design

Tablet design

Question1

For my [Arngren.net](https://www.arngren.net) redesign, the mobile and tablet layouts adapt significantly from the desktop version.

Mobile : The navigation collapses into a hamburger menu to save space, and the search bar moves below the header as a full-width element since my target users primarily browse

on mobile . Categories switch from a 4-across grid to a vertical stack with horizontal cards (image left, text right) for easy thumb scrolling. Value propositions also stack vertically with icons beside text instead of centered above.

Tablet : The tablet keeps the full navigation like desktop but switches to 3x2 grids for categories and footer instead of 4-across - this better fits portrait orientation and prevents awkward spacing. The tablet acts as a hybrid between mobile and desktop, maintaining desktop structure but adapting for touch interaction and portrait viewing

Question 2

Mobile and tablet designs require separate wireframes because they're fundamentally different experiences - not just scaled versions of desktop.

User Behavior Differs: Mobile users are task-focused with 70% of sessions lasting under 1 minute, while desktop users browse longer and conduct more research (Google Mobile Playbook, 2023). Mobile users also have different intent - "near me" searches are 3x higher on mobile (Think with Google, 2024). Multi-column layouts increase mobile cognitive load 62% (Baymard, 2023). Responsive design reimagines the experience for different contexts - 61% of users won't return to poorly optimized mobile sites (Google, 2023).
